

Documentation for package.

Package consists of three classes

1. TrailController
 - a. Contains the main required logic for spawning, activating, and pooling the trail.
 - b. Provides easy functions for activation/deactivation of the trail.
2. TrailCollision
 - a. Contains logic for setting the position and rotation of a marker in the trail
 - b. Uses raycasting for placement (will always default to the closest collision surface).
 - c. Can contain anything required for art and VFX.
3. TrailPool
 - a. Contains logic for preinstancing TrailCollision instances.
 - b. Will generate a new instance only if all instances are used by the trail.
 - c. You can replace this if you have a better object pool, but otherwise this will help with optimization.

Prefab Construction

The construction of the prefab is pretty free flowing, the main key point is that the parent object needs to have a TrailCollider attached. Then anything you wish to have spawned incrementally on the trail can be added as a child of that object.

Setup:

1. Add a TrailController to your player object.
2. Set the number of steps allowed in your trail.
3. Set the distance between each marker using SpawnDistance.
4. Set the delay before beginning deactivation using the Delay Before Deactivation field.
5. Set the delay between each TrailCollision being deactivated using Delay Inbetween Deactivations field.
6. Assign required references to the prefab type using Trail Gameobject Prefab
 - a. Note this object should have a TrailCollider attached to the parent object or else the system will fail.
7. Set the layers you wish for the trail to interact (spawn on) in the Collision Layer Mask field.
8. Set the minimum surface distance (from the player to the ground) variable
9. Set the maximum surface distance (from the player to the ground) variable
10. Set the Spawn In Air toggle if you want the trail to spawn in midair at the players given position.
